

ON TORIC POISSON STRUCTURES OF TYPE (1,1) AND THEIR COHOMOLOGY

A. CAINE, B. N. GIVENS

ABSTRACT. We classify real Poisson structures on complex toric manifolds of type (1, 1) and initiate an investigation of their Poisson cohomology. For smooth toric varieties, such structures are necessarily algebraic and are homogeneous quadratic in each of the distinguished holomorphic coordinate charts determined by the open cones of the associated simplicial fan. As an approximation to the smooth cohomology problem in each \mathbb{C}^n chart, we consider the Poisson differential on the complex of polynomial multi-vector fields. For the algebraic problem, we compute H^0 and H^1 under the assumption that the Poisson structure is generically non-degenerate. The paper concludes with numerical investigations of the higher degree cohomology groups of (\mathbb{C}^2, π_B) for various B .

1. INTRODUCTION

An almost complex structure J on a smooth manifold M determines a splitting of the complexified tangent bundle $TM \otimes_{\mathbb{R}} \mathbb{C} = T^{1,0} \oplus T^{0,1}$ into sub-bundles on which J acts by i and $-i$, respectively. This induces a decomposition

$$\wedge^2 TM \otimes_{\mathbb{R}} \mathbb{C} = (T^{1,0} \wedge T^{1,0}) \oplus (T^{1,0} \wedge T^{0,1}) \oplus (T^{0,1} \wedge T^{0,1})$$

and the smooth sections of $T^{1,0} \wedge T^{0,1}$ are termed bi-vector fields on M of type (1, 1). Observe that the canonical complex conjugation in the fibers $TM \otimes_{\mathbb{R}} \mathbb{C}$ interchanges $T^{1,0}$ and $T^{0,1}$. Thus, $T^{1,0} \wedge T^{0,1}$ is stable under the complex conjugation on $\wedge^2 TM \otimes_{\mathbb{R}} \mathbb{C}$ determined by $X \wedge Y \mapsto \overline{X} \wedge \overline{Y}$ for each X, Y in a fiber of $TM \otimes_{\mathbb{R}} \mathbb{C}$. However conjugation maps $T^{1,0} \wedge T^{1,0}$ to $T^{0,1} \wedge T^{0,1}$ and vice versa. A bi-vector field on M is real if and only if it is fixed by conjugation. So every real bi-vector field on M is a sum of a bi-vector field of type (1, 1) together with a section of $T^{1,0} \wedge T^{1,0}$ plus its conjugate. In the context of this paper, we will be concerned with complex manifolds but focus on real bi-vector fields of type (1, 1), i.e., smooth sections π of $T^{1,0} \wedge T^{0,1}$ such that $\overline{\pi} = \pi$.

Suppose that M is a complex toric manifold, i.e., a smooth complex manifold on which a complex torus $T_{\mathbb{C}}$ acts holomorphically and effectively with an open dense orbit \mathcal{O} . We write $T_{\mathbb{C}}$ for the torus, regarding it as the complexification of a real compact torus T in analogy with $\mathbb{T}_{\mathbb{C}}$ representing the non-zero complex numbers which is the complexification of the group \mathbb{T} of complex numbers of modulus 1. By a toric Poisson structure on M we mean a Poisson structure which is invariant under the action of $T_{\mathbb{C}}$. Such structures could be considered in the smooth or holomorphic category. For example, \mathbb{C}^2 with complex coordinates (z, w) is a complex toric manifold acted on by $\mathbb{T}_{\mathbb{C}}^2$ via independent dilation of each complex coordinate and one can check that $\pi = -2izw\partial_z \wedge \partial_w$ is a holomorphic toric Poisson structure. Holomorphic Poisson structures are necessarily bi-vector fields of type (2, 0). No

bi-vector field of type $(1, 1)$ can be holomorphic, nor can such a field occur as the real projection of holomorphic bi-vector field.

In this paper we will focus on the smooth category and consider structures of type $(1, 1)$ which are generically non-degenerate. For example, \mathbb{C} with coordinates (z, \bar{z}) is a complex toric manifold acted on by $\mathbb{T}_{\mathbb{C}}$ via $\zeta \cdot (z, \bar{z}) = (\zeta z, \overline{\zeta z})$ and $\pi = -2iz\bar{z}\partial_z \wedge \partial_{\bar{z}}$ is a smooth toric Poisson structure. Note that $\pi = -2iz\bar{z}\partial_z \wedge \partial_{\bar{z}}$ is real (fixed by conjugation) and of type $(1, 1)$. In terms of real variables, $z = x + iy$ and $\partial_z = \frac{1}{2}(\partial_x - i\partial_y)$ while $\partial_{\bar{z}} = \frac{1}{2}(\partial_x + i\partial_y)$ and one can check that

$$(1.1) \quad \pi = -2iz\bar{z}\partial_z \wedge \partial_{\bar{z}} = (x^2 + y^2)\partial_x \wedge \partial_y$$

which means that π is also a quadratic Poisson structure of elliptic type on \mathbb{R}^2 in the terminology of [4].

In [1], examples of toric Poisson structures of type $(1, 1)$ on smooth toric varieties generalizing this example were constructed via a quotient construction. A smooth toric variety M determines and is determined by a simplicial fan Σ in \mathfrak{t} , the real Lie algebra of the torus T , which is simplicial with respect to the coweight lattice $\Lambda \subset \mathfrak{t}$ of $T_{\mathbb{C}}$. The variety can be recovered by a quotient $\mathbb{C}^d / N_{\mathbb{C}} \simeq M$ where the dimension d and the sub-torus $N_{\mathbb{C}}$ of $\mathbb{T}_{\mathbb{C}}^d$ are determined from Σ . The double slash indicates that one does not divide \mathbb{C}^d by the action of $N_{\mathbb{C}}$ but rather a dense open $\mathbb{T}_{\mathbb{C}}^d$ -stable subset \mathcal{U}_{Σ} , determined from Σ , on which $N_{\mathbb{C}}$ acts freely. The product Poisson structure $\pi \oplus \cdots \oplus \pi$ on \mathbb{C}^d , using π from (1.1), restricts to a real toric Poisson structure on \mathcal{U}_{Σ} of type $(1, 1)$ which is generically non-degenerate and, via the quotient map $\mathcal{U}_{\Sigma} \rightarrow \mathbb{C}^d / N_{\mathbb{C}}$, coinduces a real toric Poisson structure of type $(1, 1)$ on M which is generically non-degenerate. Each open cone in Σ determines a distinguished holomorphic coordinate chart \mathbb{C}^n on M in which the action of $T_{\mathbb{C}} \simeq \mathbb{T}_{\mathbb{C}}^d / N_{\mathbb{C}}$ is equivalent to the action of $\mathbb{T}_{\mathbb{C}}^n$ on \mathbb{C}^n . In terms of such coordinates (z_1, \dots, z_n) , the Poisson structure on M has the form

$$(1.2) \quad -2i \sum_{p,q=1}^n B_{pq} z_p \bar{z}_q \partial_{z_p} \wedge \partial_{\bar{z}_q}$$

for some symmetric positive definite integral matrix $[B_{pq}]$ determined by the open cone in Σ .

Let $Z_1 = z_1 \partial_{z_1}, \dots, Z_n = z_n \partial_{z_n}$. Then we can write (1.2) in the form

$$(1.3) \quad -2i \sum_{p,q=1}^n B_{pq} Z_p \wedge \overline{Z_q}$$

making it clear that it is the image of an element of $\mathfrak{t}_{\mathbb{C}} \wedge \overline{\mathfrak{t}_{\mathbb{C}}}$ under the natural map induced infinitesimally by the holomorphic action of $T_{\mathbb{C}}$ on M . In fact, since $\mathfrak{t}_{\mathbb{C}}$ is abelian and the map from $\mathfrak{t}_{\mathbb{C}}$ into sections of $T^{1,0}$ is a homomorphism of Lie algebras, it is clear that any element of $\mathfrak{t}_{\mathbb{C}} \wedge \overline{\mathfrak{t}_{\mathbb{C}}}$ maps to a toric Poisson structure on M of type $(1, 1)$. In terms of the coordinates (z_1, \dots, z_n) , such a structure has an expression of the form (1.2) for some matrix of complex numbers $[B_{pq}]$. In order for such a Poisson structure to be real, it turns out that $[B_{pq}]$ must be hermitian and for it to be generically non-degenerate, it must be invertible. Given a formula such as (1.2) on \mathbb{C}^d , one could repeat the construction and coinduce a different real Poisson structure on a given toric variety M . From this slightly more general perspective, one can think of the construction in [1] as simply that which begins with the toric Poisson structure on \mathbb{C}^d corresponding to the identity matrix.

The purpose of this paper is to address the following natural questions regarding toric Poisson structures of type (1, 1).

- (1) To what extent does this slight modification of the construction in [1] classify all toric Poisson structures of type (1, 1)?
- (2) What is the significance, if any, of the rationality of the coefficients $[B_{pq}]$ of a toric Poisson structure as in (1.2)?
- (3) To what extent does the cohomology of a toric Poisson structure of type (1, 1) depend on the coefficient matrix $[B_{pq}]$ in each chart and the topology of the toric variety M ?

In the first section of the paper we classify real toric Poisson structures of type (1, 1) establishing the following theorem.

Theorem 1.1. *Suppose that $(M, T_{\mathbb{C}})$ is a complex toric manifold. Then the real toric Poisson structures of type (1, 1) on M are in one-to-one correspondence with the hermitian forms on $\mathfrak{t}_{\mathbb{C}}$. We denote this correspondence $\pi_B \leftrightarrow B$. Furthermore, if M is a smooth toric variety with corresponding simplicial fan Σ in \mathfrak{t} , then in each distinguished holomorphic coordinate chart on M associated to an open cone of the fan for M , π_B has the form (1.2) where $[B_{pq}]$ is the matrix representing B with respect to the integral basis spanning the cone.*

The formulas for π_B in each of the distinguished holomorphic coordinate charts are then given by (1.2) for different matrices $[B_{pq}]$ which are congruent by elements of $GL(n, \mathbb{Z})$. Such structures are generically non-degenerate if and only if the hermitian form B is non-degenerate. We show in the following section that those forms which are rational with respect to the co-weight lattice Λ in $\mathfrak{t}_{\mathbb{C}}$ then have an additional symmetry.

Theorem 1.2. *Suppose that $(M, T_{\mathbb{C}})$ is a complex toric manifold and that π_B is a generically non-degenerate real toric Poisson structure of type (1, 1) on M with associated to a non-degenerate hermitian form B on $\mathfrak{t}_{\mathbb{C}}$. Then the action of $T_{\mathbb{C}}$ on the open orbit \mathcal{O} is hamiltonian with respect to π_B if and only if B is rational with respect to the coweight lattice $\Lambda \subset \mathfrak{t}_{\mathbb{C}}$.*

In the remaining sections of the paper, we initiate an investigation of the cohomology of such structures, focusing on $M = \mathbb{C}^2$ and various example forms B in an effort to begin addressing the much harder third question. These examples remove topology from consideration because \mathbb{C}^2 is contractible and focus only on contributions to the cohomology from the degeneracies of the Poisson tensor. Since toric Poisson structures are algebraic in the distinguished coordinate charts, we consider the cohomology problem first in the algebraic category and use symbolic computation with Mathematica to compute the cohomology for multivector fields of low monomial degree. These numerical results suggest that the cohomology of (\mathbb{C}^2, π_B) is quite small for generic B and, in particular, is finite dimensional. However, additional independent classes in various degrees can occur as for the examples in [1]. Rather surprisingly, we found an example of a (\mathbb{C}^2, π_B) where B is symmetric positive definite and integral, yet the cohomology is infinite dimensional, having infinitely many generators in wedge degrees 3 and 4. This example is the local form of the toric Poisson structure constructed in [1] on one of the Hirzebruch surfaces. In general, classes in $H^0(M, \pi)$, $H^1(M, \pi)$, and $H^2(M, \pi)$ have well-known interpretations, but the interpretation of non-trivial classes of higher wedge degree is unclear.

If π is a generically non-degenerate real toric Poisson structure of type $(1, 1)$ on a complex toric manifold X , it is easy to see that $H^0(M, \pi) = \mathbb{C}\langle 1 \rangle$ if X is connected. It is a more subtle fact that $\mathfrak{t}_{\mathbb{C}}$ includes in $H^1(M, \pi)$ as a real subspace if the fan for M is closed in \mathfrak{t} . The main result of the later sections is that there is nothing more in $H^1(\mathbb{C}^n, \pi_B)$ when B is non-degenerate, at least in the algebraic category.

$$H^1(\mathbb{C}^n, \pi_B) \simeq \mathfrak{t}_{\mathbb{C}}$$

In a forthcoming paper, we will use representation theory to completely determine the Poisson cohomology of (\mathbb{C}^n, π_B) , reducing the determination of generators for the cohomology to the solution of certain Diophantine inequalities depending on the matrix B . This paper, in part, serves as an advertisement of those results.

Let T denote a compact connected abelian Lie group of real dimension n , i.e. a compact torus, and let $T_{\mathbb{C}}$ denote its complexification. The kernel of the group homomorphism $\mathfrak{t}_{\mathbb{C}} \rightarrow T_{\mathbb{C}}$ defined by $\xi \mapsto \exp(\xi)$ is the coweight lattice $\Lambda \subset \mathfrak{t} \subset \mathfrak{t}_{\mathbb{C}}$. If we choose a basis ξ_1, \dots, ξ_n for Λ and define a \mathbb{Z} -linear map $(\tau i \mathbb{Z})^n \rightarrow \Lambda$ by $\tau i e_k \mapsto \xi_k$, then by extending to a \mathbb{C} -linear map $\mathbb{C}^n \rightarrow \mathfrak{t}_{\mathbb{C}}$ we obtain a commutative diagram

$$\begin{array}{ccccccc}
0 & \longrightarrow & (\tau i\mathbb{Z})^n & \longrightarrow & \mathbb{C}^n & \xrightarrow{e(\cdot)} & (\mathbb{T}_{\mathbb{C}})^n \longrightarrow 1 \\
& & \downarrow & & \downarrow & & \vdots \\
0 & \longrightarrow & \Lambda & \longrightarrow & \mathfrak{t}_{\mathbb{C}} & \xrightarrow{\exp(\cdot)} & T_{\mathbb{C}} \longrightarrow 1
\end{array}$$

$$\exp(\frac{s_1}{\tau_1^i} \xi_1 + \cdots + \frac{s_n}{\tau_n^i} \xi_n) = \exp(\frac{s_1}{\tau_1^i} \xi_1) \cdots \exp(\frac{s_n}{\tau_n^i} \xi_n)$$

in $T_{\mathbb{C}}$.

Notation 1.4. For $z \neq 0$ in \mathbb{C} and $\xi \in \Lambda$, we write z^ξ for $\exp(\frac{1}{\tau i} \log(z)\xi) \in T_{\mathbb{C}}$. This is well defined because $\exp(k\xi) = 1$ for each $k \in \mathbb{Z}$. Thus, for a choice of basis ξ_1, \dots, ξ_n of Λ , we obtain an isomorphism $(T_{\mathbb{C}})^n \rightarrow T_{\mathbb{C}}$ given by $(z_1, \dots, z_n) \mapsto z_1^{\xi_1} \dots z_n^{\xi_n}$.

2. REAL TORIC POISSON STRUCTURES OF TYPE (1,1)

Let $(M, T_{\mathbb{C}})$ be a complex toric manifold and choose a \mathbb{C} -basis ξ_1, \dots, ξ_n for $\mathfrak{t}_{\mathbb{C}}$. Then through the holomorphic action of $T_{\mathbb{C}}$ we obtain corresponding holomorphic $T_{\mathbb{C}}$ -invariant vector fields X_1, \dots, X_n on M , i.e., holomorphic sections of $T^{1,0}$, which are $T_{\mathbb{C}}$ -invariant. Given a hermitian matrix of complex numbers, one can use this data to construct a real toric Poisson structure on M of type (1,1).

Lemma 2.1. *If $[B_{pq}]$ is a hermitian matrix of complex numbers, then*

$$(2.1) \quad \pi = 2i \sum_{p,q=1}^n B_{pq} X_p \wedge \overline{X_q}$$

is a real toric Poisson structure on M of type (1,1).

Proof. By construction, π_B is a $T_{\mathbb{C}}$ -invariant bi-vector field on M on type (1,1). Since

$$\begin{aligned} \overline{\pi_B} &= 2i \sum_{p,q=1}^n \overline{B_{pq} X_p \wedge \overline{X_q}} = -2i \sum_{p,q=1}^n \overline{B_{pq}} \overline{X_p} \wedge X_q \\ &= 2i \sum_{p,q=1}^n \overline{B_{pq}} X_q \wedge \overline{X_p} = 2i \sum_{p,q=1}^n \overline{B_{qp}} X_p \wedge \overline{X_q} \end{aligned}$$

we see that π_B is real ($\overline{\pi_B} = \pi_B$) because $\overline{B_{qp}} = B_{pq}$ for each $p, q = 1, \dots, n$. The holomorphic action of $T_{\mathbb{C}}$ on M induces a homomorphism of Lie algebras $\mathfrak{t}_{\mathbb{C}} \rightarrow T^{1,0}$ and this carries $\xi_p \rightarrow X_p$ for each p by definition. Thus, $[X_p, X_{p'}] = 0$ for each $p, p' = 1, 2, \dots, n$. Since conjugation preserves brackets, we know that $[\overline{X_q}, \overline{X_{q'}}] = 0$ for all $q, q' = 1, 2, \dots, n$. Recalling that holomorphic derivations and anti-holomorphic derivations commute, we find that $[X_p, \overline{X_q}] = 0$ for all $p, q = 1, 2, \dots, n$. Thus π_B is a linear combination of wedge products of commuting vector fields and hence $[\pi_B, \pi_B] = 0$ by linearity and the graded Leibniz rule for the Schouten bracket. \square

The next result shows that every real toric Poisson structure of type (1,1) on M is of the form π_B . The representation (2.1) depends on the basis ξ_1, \dots, ξ_n which determines both the holomorphic vector fields X_1, \dots, X_n and, as we will see, the matrix $[B_{pq}]$.

Theorem 2.2. *Suppose that π is a real toric Poisson structure on M of type (1,1). For each \mathbb{C} -basis ξ_1, \dots, ξ_n of $\mathfrak{t}_{\mathbb{C}}$ there exists an $n \times n$ Hermitian matrix $[B_{pq}]$ such that $\pi = \pi_B$ as in (2.1).*

Proof. The key point is that a \mathbb{C} -basis ξ_1, \dots, ξ_n for $\mathfrak{t}_{\mathbb{C}}$ determines a frame X_1, \dots, X_n for $T^{1,0}$ over the open dense $T_{\mathbb{C}}$ -orbit \mathcal{O} . This is because the action of $T_{\mathbb{C}}$ is free and transitive on \mathcal{O} . By conjugation, $\overline{X_1}, \dots, \overline{X_n}$ is then a frame for $T^{0,1}$ over \mathcal{O} . Consequently, the bi-vector fields $X_p \wedge \overline{X_q}$ for $p, q = 1, 2, \dots, n$ form a frame for

$T^{1,0} \wedge T^{0,1}$ over \mathcal{O} . Thus, there exist smooth complex valued functions B_{pq} on \mathcal{O} such that

$$(2.2) \quad \pi = 2i \sum_{p,q=1}^n B_{pq} X_p \wedge \overline{X_q}$$

on \mathcal{O} . As we saw in the proof of Lemma 2.1, (2.2) implies that

$$\overline{\pi} = 2i \sum_{p,q=1}^n \overline{B_{qp}} X_p \wedge \overline{X_q}$$

on \mathcal{O} . Since π is real, we can match coefficients to conclude that $B_{pq} = \overline{B_{qp}}$ for each $p, q = 1, \dots, n$, so that $[B_{pq}]$ is a hermitian matrix of functions. It remains to show that these functions are constant.

If π is also $T_{\mathbb{C}}$ -invariant, then the Schouten bracket $[X_r, \pi] = 0$ for each $r = 1, \dots, n$. Observe that

$$\begin{aligned} [X_r, B_{pq} X_p \wedge \overline{X_q}] &= X_r(B_{pq}) X_p \wedge \overline{X_q} + B_{pq} [X_r, X_p] \wedge \overline{X_q} - B_{pq} X_p \wedge [X_r, \overline{X_q}] \\ &= X_r(B_{pq}) X_p \wedge \overline{X_q} \end{aligned}$$

because the Schouten bracket is a graded derivation. Thus, $[X_r, \pi] = 0$ on $\mathbb{T}_{\mathbb{C}}^n$ for each $r = 1, \dots, n$ if and only if $X_r(B^{pq}) = 0$ on \mathcal{O} for each $p, q, r = 1, \dots, n$. Hence, each B_{pq} is anti-holomorphic on \mathcal{O} . Likewise, the fact that $[\overline{X_r}, \pi] = 0$ for all $r = 1, \dots, n$ can be used to argue that B_{pq} is also holomorphic on \mathcal{O} . Therefore, each B_{pq} is constant on \mathcal{O} . But since the vector fields X_p and $\overline{X_q}$ are smooth on M and the functions B_{pq} are constant on the open dense set \mathcal{O} , the representation (2.2) is actually valid on all of M . Hence $\pi = \pi_B$ on M as desired. \square

Proposition 2.3. *If $\pi = \pi_B$ is a real toric Poisson structure of type $(1, 1)$ on M which is generically non-degenerate, then $[B_{pq}]$ is invertible.*

Proof. Since π_B is $T_{\mathbb{C}}$ -invariant,

$$\pi_B^n = (2i)^n \det([B_{pq}]) X_1 \wedge \cdots \wedge X_n \wedge \overline{X_1} \wedge \cdots \wedge \overline{X_n}$$

is $T_{\mathbb{C}}$ -invariant. Since $X_1 \wedge \cdots \wedge X_n \wedge \overline{X_1} \wedge \cdots \wedge \overline{X_n}$ is non-zero on \mathcal{O} we conclude that $\det([B_{pq}]) \neq 0$ on \mathcal{O} if π is generically non-degenerate. Hence $[B_{pq}]$ is invertible. \square

Remark 2.4. By applying Theorem 2.2 for a different choice of basis ξ'_1, \dots, ξ'_n of $\mathfrak{t}_{\mathbb{C}}$, one obtains another hermitian matrix $[B'_{pq}]$ such that $\pi = \pi_{B'}$. One can check that the matrices $[B_{pq}]$ and $[B'_{pq}]$ are congruent via the change of basis matrix from ξ_1, \dots, ξ_n to ξ'_1, \dots, ξ'_n . Thus, these matrices represent the same hermitian form on $\mathfrak{t}_{\mathbb{C}}$. The first half of Theorem 1.1 from the introduction has now been established. The real toric Poisson structures on M of type $(1, 1)$ are in one-to-one correspondence with the hermitian forms on $\mathfrak{t}_{\mathbb{C}}$.

If M is a smooth compact toric variety with associated simplicial fan Σ in \mathfrak{t} , then we obtain a distinguished family of holomorphic coordinate charts on M , one for each open cone in Σ . Such a cone is spanned by a \mathbb{Z} -basis ξ_1, \dots, ξ_n of the coweight lattice Λ in \mathfrak{t} and with this basis we obtain an isomorphism $\mathbb{T}_{\mathbb{C}}^n \rightarrow T_{\mathbb{C}}$ given by $(z_1, \dots, z_n) \mapsto z_1^{\xi_1} \cdots z_n^{\xi_n}$ as in Notation 1.4. By choosing a point $x \in \mathcal{O}$, we obtain a map $\mathbb{T}_{\mathbb{C}}^n \rightarrow T_{\mathbb{C}}.x = \mathcal{O}$ and holomorphic coordinates on \mathcal{O} . In terms of

these coordinates, the holomorphic vector fields X_1, \dots, X_n associated to ξ_1, \dots, ξ_n have the form $X_p = z_p \partial_{z_p}$. Thus

$$(2.3) \quad \pi = i \sum_{p,q=1}^n B^{pq} z_p \bar{z}_q \partial_{z_p} \wedge \partial_{\bar{z}_q}$$

in these coordinates.

In [1], local forms such as these were obtained for Poisson structures on smooth toric varieties which were coinduced from a product Poisson structure on \mathbb{C}^d via a quotient construction. There, however, the matrices $[B^{pq}]$ were also integral and thus associated to integral hermitian forms on $\mathfrak{t}_{\mathbb{C}}$. We will next show that toric Poisson structures of type (1,1) associated to non-degenerate hermitian forms which are rational with respect to Λ are precisely those for which the action of $T_{\mathbb{C}}$ on \mathcal{O} is Hamiltonian.

The sense in which we will consider the action to be Hamiltonian is the following from [5]. Regarding $T_{\mathbb{C}}$ as a Poisson Lie group with the trivial Poisson Lie group structure, we can think of the action $(\mathcal{O}, \pi_B) \times (T_{\mathbb{C}}, 0) \rightarrow (\mathcal{O}, \pi_B)$ as a Poisson action and search for a momentum mapping for the action taking values in the dual Poisson Lie group. However, we must specify which model of the dual group we are considering. Since $T_{\mathbb{C}}$ is abelian, the simply connected model for the dual group is simply the vector space $(\mathfrak{t}_{\mathbb{C}})^*$. But an alternative is the quotient $(\mathfrak{t}_{\mathbb{C}})^*/\Lambda^*$, where $\Lambda^* = \text{Hom}(\Lambda, \mathbb{Z})$, which is isomorphic to $T_{\mathbb{C}}$ or any other discrete quotient of $\mathfrak{t}_{\mathbb{C}}$. With this model, we can regard $(T_{\mathbb{C}}, 0)$ as a self-dual Poisson Lie group. Our final goal in this section is to classify which π_B admit such a momentum map with values in $T_{\mathbb{C}}$ or some discrete quotient of $\mathfrak{t}_{\mathbb{C}}$.

Suppose that $(N, \pi) \times (G, \pi_G) \rightarrow (N, \pi)$ is a Poisson action of a Poisson Lie group (G, π_G) on a Poisson manifold (N, π) . Let $\mu: N \rightarrow G^*$ be a smooth map from (N, π) to a dual group G^* of (G, π_G) . Recall that μ is a G^* -valued *momentum map* if for each $\xi \in \mathfrak{g}$, the Lie algebra of G ,

$$(2.4) \quad X_{\xi} = \pi^{\#}(\mu^*(\theta_{\xi}))$$

where X_{ξ} is the vector field on N generated by the infinitesimal action of ξ , θ_{ξ} is the right-invariant 1-form on G^* generated by $\xi \in \mathfrak{g} = (T_e G^*)^*$, and $\mu^*: T^* G^* \rightarrow T^* N$ is the cotangent lift of $\mu: N \rightarrow G^*$. We will say that a Poisson action of (G, π_G) on (N, π) is G^* -Hamiltonian if there exists a G^* -valued momentum map for the action.

Theorem 2.5. *Suppose π_B is a real toric Poisson structure on M of type (1,1) associated to a non-degenerate Hermitian form B on $\mathfrak{t}_{\mathbb{C}}$. Then the action of $T_{\mathbb{C}}$ on \mathcal{O} is $T_{\mathbb{C}}$ -hamiltonian if and only if B is rational with respect to Λ in $\mathfrak{t}_{\mathbb{C}}$.*

Proof. We will compute in the global coordinates (z_1, \dots, z_n) for \mathcal{O} associated to an integral basis ξ_1, \dots, ξ_n for Λ . This identifies \mathcal{O} with $\mathbb{T}_{\mathbb{C}}^n$ and ensures that π_B has the form (2.3) where $[B_{pq}]$ is the matrix representing B in terms of that basis. Furthermore, we can regard $T_{\mathbb{C}}$ as $\mathbb{T}_{\mathbb{C}}^n$ acting on $\mathbb{T}_{\mathbb{C}}^n$ by multiplication. So, to specify a $G^* = T_{\mathbb{C}}$ -valued momentum map on \mathcal{O} is the same as specifying a map $\mu: \mathbb{T}_{\mathbb{C}}^n \rightarrow \mathbb{T}_{\mathbb{C}}^n$ satisfying the differential condition (2.4). To proceed, we will classify the local solutions μ to (2.4) and show that these local solutions can be extended globally to $\mathbb{T}_{\mathbb{C}}^n$ if and only if $[B_{pq}]$ is an rational matrix.

If $\xi = x_1 e_1 + \dots + x_n e_n$ and $\eta = y_1 e_1 + \dots + y_n e_n$ in \mathbb{C}^n , let $\langle \xi, \eta \rangle = \sum_{k=1}^n \bar{x}_k y_k$ so that $\langle \cdot, \cdot \rangle$ is the standard hermitian inner product on \mathbb{C}^n which is conjugate linear

in its first argument. We will identify the real dual of \mathbb{C}^n with \mathbb{C}^n using $\text{Im}\langle \cdot, \cdot \rangle$. Then $\xi \in \mathbb{C}^n$ with $\xi = \sum_{k=1}^n x_k e_k$ generates a holomorphic vector field X_ξ on \mathcal{O} and the invariant 1-form

$$(2.5) \quad \theta_\xi = \text{Re} \left(\sum_{k=1}^n \overline{ix_k} \frac{dw_k}{w_k} \right)$$

on the dual group $G^* = \mathbb{T}_{\mathbb{C}}^n$ with coordinates (w_1, \dots, w_n) . To verify that this formula for θ_ξ is correct, observe that θ_ξ is invariant under multiplication by $(\zeta_1, \dots, \zeta_n) \in \mathbb{T}_{\mathbb{C}}^n$ and restricts to the form $\text{Re}\langle i\xi, \cdot \rangle = \text{Im}\langle \xi, \cdot \rangle$ at the identity.

Let $[B^{pq}]$ denote the matrix inverse to $[B_{pq}]$, so that $[\overline{B^{pq}}]$ is the matrix representing the conjugate hermitian form dual to B on $\mathfrak{t}_{\mathbb{C}}^*$. We set

$$(2.6) \quad \mu(z_1, \dots, z_n) = \left(z_1^{\overline{B^{11}}} \dots z_n^{\overline{B^{nn}}}, \dots, z_1^{\overline{B^{1n}}} \dots z_n^{\overline{B^{nn}}} \right) = (w_1, \dots, w_n)$$

and obtain a multi-valued function on $M = \mathbb{T}_{\mathbb{C}}^n$ with values in $\mathbb{T}_{\mathbb{C}}^n$. We will show that μ is the unique solution to (2.4) satisfying $\mu(1, \dots, 1) = (1, \dots, 1)$. By inspection, we see that μ can be interpreted as a single-valued function on $M = \mathbb{T}_{\mathbb{C}}^n$ with values in a finite sheeted cover of $T_{\mathbb{C}}$ if and only if each $\overline{B^{pq}}$ is rational. But this of course requires that each B_{pq} be rational as well.

Observe that

$$\mu^* \left(\frac{dw_k}{w_k} \right) = \frac{d(z_1^{\overline{B^{1k}}} \dots z_n^{\overline{B^{nk}}})}{z_1^{\overline{B^{k1}}} \dots z_n^{\overline{B^{kn}}}} = \sum_{j=1}^n \overline{B^{jk}} \frac{dz_j}{z_j}$$

for each $k = 1, 2, \dots, n$. Thus,

$$\mu^*(\theta_\xi) = \text{Re} \left(\sum_{k=1}^n \overline{ix_k} \left(\sum_{j=1}^n \overline{B^{jk}} \frac{dz_j}{z_j} \right) \right) = \text{Re} \left(\sum_{j,k=1}^n \overline{ix_k} B^{kj} \frac{dz_j}{z_j} \right)$$

because $[B^{jk}]$ is hermitian. Applying $\pi_B^\#$ from (2.3), we obtain

$$(2.7) \quad \pi_B^\#(\mu^*(\theta_\xi)) = \pi_B^\# \left(\text{Re} \left(\sum_{j,k=1}^n \overline{ix_k} B^{kj} \frac{dz_j}{z_j} \right) \right)$$

$$(2.8) \quad = \text{Re} \left(\pi_B^\# \left(\sum_{j,k=1}^n \overline{ix_k} B^{kj} \frac{dz_j}{z_j} \right) \right)$$

since $\pi_B^\#$ is real. Now,

$$\begin{aligned} \pi_B^\# \left(\sum_{j,k=1}^n \overline{ix_k} B^{kj} \frac{dz_j}{z_j} \right) &= 2 \sum_{p,q=1}^n \sum_{j,k=1}^n B_{pq} B^{kj} \frac{\bar{x}_k z_p \bar{z}_q}{z_j} (\partial_{z_p} \wedge \partial_{\bar{z}_q})^\# (dz_j) \\ &= 2 \sum_{p,q=1}^n \sum_{j,k=1}^n B_{pq} B^{kj} \frac{\bar{x}_k z_p \bar{z}_q}{z_j} \delta_{pj} \partial_{\bar{z}_q} \\ &= 2 \sum_{p,q=1}^n \sum_{k=1}^n B_{pq} B^{kp} \bar{x}_k \bar{z}_q \partial_{\bar{z}_q} \\ &= 2 \sum_{k=1}^n \bar{x}_k \bar{z}_k \partial_{\bar{z}_k} \end{aligned} \quad (2.9)$$

since $[B^{kp}][B_{pq}] = [\delta_p^k]$. Combining (2.8) and (2.9), we have

$$\pi_B^\#(\mu^*(\theta_\xi)) = \operatorname{Re} \left(2 \sum_{k=1}^n \bar{x}_k \bar{z}_k \partial_{\bar{z}_k} \right) = \sum_{k=1}^n x_k z_k \partial_{z_k} + c.c. = 2\operatorname{Re}(X_\xi)$$

as required.

Thus, μ is locally a solution to (2.4). All other solutions differ from μ by post-multiplication by an element $(\zeta_1, \dots, \zeta_n)$ of $\mathbb{T}_\mathbb{C}^n$ which ensures that $(1, \dots, 1) \mapsto (\zeta_1, \dots, \zeta_n)$. This completes the proof. \square

Example 2.6. For $\pi_b = -2ibz\bar{z}\partial_z \wedge \partial_{\bar{z}}$ on $\mathbb{T}_\mathbb{C}$, $b \in \mathbb{R} \setminus \{0\}$, the map $\mu(z) = z^{\frac{1}{b}}$ satisfies the differential condition (2.4) with respect to the infinitesimal action of $\mathbb{T}_\mathbb{C}$ on itself. However, μ is single-valued only if $\frac{1}{b} \in \mathbb{Z}$. For general $b = \frac{m}{n} \in \mathbb{Q}$, this can be remedied by replacing the codomain $\mathbb{T}_\mathbb{C}$ of μ with a finite sheeted covering of $\mathbb{T}_\mathbb{C}$. Since each of those covers are isomorphic to $\mathbb{T}_\mathbb{C}$, this does not substantially change the model for the dual group.

3. ALGEBRAIC POISSON COHOMOLOGY

In complex dimension $n = 1$, there are three examples of complex toric manifolds, namely $\mathbb{T}_\mathbb{C}$, $\mathbb{C} = \mathbb{T}_\mathbb{C} \cup \{0\}$, or $\mathbb{C}P^1 = \mathbb{C} \cup \{\infty\}$. Applying Theorem 1.1, the real toric Poisson structures of type (1,1) have the form

$$(3.1) \quad \pi_b = -2ibz\bar{z}\partial_z \wedge \partial_{\bar{z}}$$

for some $b \in \mathbb{R}$ with $b \neq 0$ in terms of the holomorphic coordinate on $\mathbb{T}_\mathbb{C}$. In terms of the underlying real variables $z = x + iy$, this Poisson structure has the expression

$$\pi_b = b(x^2 + y^2)\partial_x \wedge \partial_y.$$

In the example $M = \mathbb{C}$, it is therefore quadratic plane Poisson structure of elliptic type. On $\mathbb{R}^2 \setminus \{(0,0)\} = \mathbb{T}_\mathbb{C}$ it is non-degenerate and so its Poisson cohomology is isomorphic the de Rham cohomology of $\mathbb{R}^2 \setminus \{(0,0)\}$. In [7], Nakanishi performed a careful analysis of the partial differential equations encoded in the condition $\sigma(Y) = 0$, where σ is the Poisson differential for π_b and Y is a smooth multivector field on \mathbb{R}^2 , and through that analysis determined the Poisson cohomology of π_b on \mathbb{C} . Since the expression (3.1) is invariant under the change of variables $z \mapsto 1/z$, a Mayer-Vietoris argument can then be applied to compute the Poisson cohomology of π_b on $\mathbb{C}P^1$ using Nakanishi's result on $\mathbb{T}_\mathbb{C} \cup \{0\} = \mathbb{C}$ and $\mathbb{T}_\mathbb{C} \cup \{\infty\} \simeq \mathbb{C}$. This was observed in [1]. In each case, the result is independent of b , but is very different depending on whether the domain is $\mathbb{T}_\mathbb{C}$, \mathbb{C} , or $\mathbb{C}P^1$. This is because Poisson cohomology is affected both by the topology of M and the degeneracy of the Poisson tensor. Rather surprisingly, in each of these cases the Poisson cohomology was found to be finite dimensional and, perhaps more surprisingly, it was possible to find algebraic representatives for the Poisson cohomology classes.

As an approximation to the smooth cohomology problem, we consider the algebraic cohomology of π_B on \mathbb{C}^n for more general n . With the algebraic cohomology in hand, one might hope to compute the smooth cohomology by taking some sort of limit. Then for smooth toric varieties, which have a distinguished finite atlas of affine charts in which any toric Poisson structure of type (1,1) has the form (2.3), one could hope to assemble the global smooth cohomology from the local results using a Mayer-Vietoris argument.

The algebraic Poisson cohomology of (\mathbb{C}^n, π_B) is the cohomology of the differential graded algebra $\mathcal{V}^{\mathbb{R}} = \mathbb{R}[x_1, y_1, \dots, x_n, y_n] \otimes \bigwedge \mathbb{R}\langle \partial_{x_1}, \partial_{y_1}, \dots, \partial_{x_n}, \partial_{y_n} \rangle$, the exterior algebra of multi-vector fields on \mathbb{C}^n (viewed as \mathbb{R}^{2n}) with polynomial coefficients. The differential $\sigma: \mathcal{V}^{\mathbb{R}} \rightarrow \mathcal{V}^{\mathbb{R}}$ is given by $\sigma(Y) = [Y, \pi_B]$, where $[\cdot, \cdot]$ is the Schouten bracket. Since π_B is homogeneous quadratic, σ on the space of smooth multi-vector fields leaves invariant the subspace of multi-vector fields with polynomial coefficients. It will be convenient to complexify the problem so that we can work with complex coordinates z_k and \bar{z}_k instead of the real coordinates x_k and y_k . Let

$$\mathcal{V} = \mathcal{V}^{\mathbb{R}} \otimes_{\mathbb{R}} \mathbb{C} \simeq \mathbb{C}[x_1, y_1, \dots, x_n, y_n] \otimes \bigwedge \mathbb{C}\langle \partial_{x_1}, \partial_{y_1}, \dots, \partial_{x_n}, \partial_{y_n} \rangle.$$

Then the assignments $z_k \mapsto x_k + iy_k$, $\bar{z}_k \mapsto x_k - iy_k$, $\partial_z \mapsto \frac{1}{2}(\partial_{x_k} - i\partial_{y_k})$, and $\partial_{\bar{z}_k} \mapsto \frac{1}{2}(\partial_{x_k} + i\partial_{y_k})$ determine an isomorphism

$$\mathcal{V} \simeq \mathbb{C}[z_1, \dots, z_n, \bar{z}_1, \dots, \bar{z}_n] \otimes \bigwedge \mathbb{C}\langle \partial_{z_1}, \dots, \partial_{z_n}, \partial_{\bar{z}_1}, \dots, \partial_{\bar{z}_n} \rangle$$

which carries the real coordinate expression for π_B to the complex coordinate expression for π_B . But then, at this algebraic level, computing the real algebraic cohomology of (\mathbb{C}^n, π_B) with complex coefficients is the same computing the complex algebraic cohomology of (\mathbb{C}^{2n}, π_B) where

$$(3.2) \quad \pi_B = -2i \sum_{p,q=1}^n B_{pq} z_p w_q \partial_{z_p} \wedge \partial_{w_q}$$

in terms of the complex linear coordinates $(z_1, \dots, z_n, w_1, \dots, w_n)$. Indeed, the assignments $w_k \mapsto \bar{z}_k$ determine an isomorphism of DGAs from the complex algebraic complex for (\mathbb{C}^{2n}, π_B) to the real algebraic complex for (\mathbb{C}^n, π_B) but with complex coefficients.

Since the Poisson differential is linear in its dependence on the Poisson structure, modifying the Poisson structure by an overall non-zero scalar factor does not affect the cohomology. So the factor of $-2i$ in (3.2) may be ignored. Thus, we consider the general problem of computing the cohomology of the DGA whose algebra is the exterior algebra $R \otimes \bigwedge V$ over $R = \mathbb{C}[z_1, \dots, z_n, w_1, \dots, w_n]$, where $V = \mathbb{C}\langle \partial_{z_1}, \dots, \partial_{z_n}, \partial_{w_1}, \dots, \partial_{w_n} \rangle$, equipped with the differential σ over \mathbb{C} defined by $\sigma(Y) = [Y, \pi]$ for each $Y \in R \otimes \bigwedge V$ and

$$(3.3) \quad \pi_B = \sum_{p,q=1}^n B_{pq} z_p w_q \partial_{z_p} \wedge \partial_{w_q}$$

for some hermitian matrix $[B_{pq}]$. We will be concerned primarily with examples where $[B_{pq}]$ is invertible, so that π is generically non-degenerate and the cohomology has a chance at being finite dimensional.

3.1. General Results for H^0 and H^1 . The first general result on the cohomology concerns H^0 , which we recall is canonically isomorphic to the subspace elements of $\ker \sigma$ of wedge degree 0.

Proposition 3.1. *If $[B_{pq}]$ in (3.3) is invertible, so that π_B is generically non-degenerate, then $H^0(\mathbb{C}^{2n}, \pi_B) = \mathbb{C}\langle 1 \rangle$.*

Proof. If $[B_{pq}]$ is invertible, then π_B is non-degenerate on the open dense set $\mathbb{T}_{\mathbb{C}}^{2n} \subset \mathbb{C}^{2n}$ by a computation similar to that in the proof of Prop. 2.3. The complex algebraic functions f on \mathbb{C}^{2n} with $[f, \pi_B] = 0$ are those for which $\pi_B^{\#}(\partial f) = 0$ on

\mathbb{C}^{2n} , where ∂ is the Dolbeault operator. Such functions satisfy $\pi_B^\#(\partial f) = 0$ on $\mathbb{T}_{\mathbb{C}}^{2n}$ in particular. Since $\mathbb{T}_{\mathbb{C}}^{2n}$ is connected and π_B is non-degenerate there, we see that this requires f to be constant. But an algebraic function which is constant on $\mathbb{T}_{\mathbb{C}}^{2n}$ is constant on \mathbb{C}^{2n} . Hence $H^0(\mathbb{C}^{2n}, \pi_B) = \mathbb{C}\langle 1 \rangle$ for the algebraic cohomology. \square

This argument certainly applies to holomorphic functions, so the same result is valid in the holomorphic category. By setting $w_k = \bar{z}_k$, re-inserting the factor of $-2i$ in π_B , and considering not the Dolbeault operator ∂ but the full de Rham differential $d = \partial + \bar{\partial}$, the above argument applies to smooth real problem as well. Furthermore, it applies to any complex toric manifold M equipped with a generically non-degenerate real toric Poisson structure π of type (1,1). Since π is non-degenerate on the open dense $T_{\mathbb{C}}$ -orbit \mathcal{O} , which is diffeomorphic to $T_{\mathbb{C}}$, only the constant functions on M can be constant on the symplectic leaves of (M, π) by continuity.

The classes in $H^1(M, \pi)$ are infinitesimal outer automorphisms of (M, π) , i.e., classes of vector fields which preserve π ($[X, \pi] = 0$) modulo those which do so because they are hamiltonian ($X = \pi^\#(df)$). The standard basis for \mathbb{C}^{2n} , thought of as the Lie algebra of $\mathbb{T}_{\mathbb{C}}^{2n}$, determines the holomorphic vector fields $z_1\partial_{z_1}, \dots, z_n\partial_{z_n}, w_1\partial_{w_1}, \dots, w_n\partial_{w_n}$ on \mathbb{C}^{2n} . Such vector fields preserve π_B in (3.3) because π_B is a linear combination of wedge products of these fields. The fields are locally, but not globally, hamiltonian because their primitives involve $\log(z_k)$ or $\log(w_k)$ which are not even single valued on $\mathbb{T}_{\mathbb{C}}^{2n}$ let alone extend to $z_k = 0$ or $w_k = 0$. In the algebraic category, a polynomial hamiltonian then does not exist. Rather surprisingly, every other polynomial vector field in the kernel has a polynomial hamiltonian.

Theorem 3.2. *If $[B_{pq}]$ in (3.3) is symmetric and invertible, then*

$$H^1(\mathbb{C}^{2n}, \pi_B) = \mathbb{C}\langle z_1\partial_{z_1}, \dots, z_n\partial_{z_n}, w_1\partial_{w_1}, \dots, w_n\partial_{w_n} \rangle$$

for the algebraic cohomology.

Proof. We start by computing the action of σ on the natural \mathbb{C} -basis elements of $R \otimes \bigwedge V$, i.e., those elements of the form $z^\alpha w^\beta \partial_{z_j}$ or $z^\alpha w^\beta \partial_{w_k}$. A straightforward computation with the Schouten bracket shows that

$$(3.4) \quad \sigma(z^\alpha w^\beta \partial_{z_k}) = z^\alpha w^\beta \partial_{z_k} \wedge \left(\sum_{p=1}^n (B_p \cdot \beta) z_p \partial_{z_p} - \sum_{q=1}^n (B_q \cdot (\alpha - e_k)) w_q \partial_{w_q} \right)$$

and likewise

$$(3.5) \quad \sigma(z^\alpha w^\beta \partial_{w_k}) = z^\alpha w^\beta \partial_{w_k} \wedge \left(\sum_{p=1}^n (B_p \cdot (\beta - e_k)) z_p \partial_{z_p} - \sum_{q=1}^n (B_q \cdot \alpha) w_q \partial_{w_q} \right)$$

for each $\alpha, \beta \in \mathbb{N}^n$ and $k = 1, 2, \dots, n$, where B_p denotes the p^{th} row or column of B .

Let us next observe that we can decompose a general linear combination of basis elements in a useful manner. To describe the decomposition, it will be convenient to briefly suppress the splitting of variables into z and w and instead using a single variable ζ for both: we write $X = \sum c_\mu^k \zeta^\mu \partial_{\zeta_k}$, where $\mu = (\alpha, \beta)$, $\zeta_k = z_k$ if $k \leq n$

or w_{k-n} if $k > n$, and $\zeta^\mu = z^\alpha w^\beta$. We partition the terms of X by defining

$$X_\lambda = \sum_{\substack{\mu, k \\ \mu = \lambda + e_k}} c_\mu^k \zeta^\mu \partial_{\zeta_k},$$

as λ ranges over integral vectors of length $2n$. Note that $X_\lambda \neq 0$ for only finitely many λ . Furthermore, an inspection of (3.4) and (3.5) reveals that if λ and λ' are distinct, then $\sigma(X_\lambda)$ and $\sigma(X_{\lambda'})$ have no like terms, that is, no terms with the same wedge and homogeneous degrees. This means that if $\sigma(X) = 0$, then $\sigma(X_\lambda) = 0$ for each λ .

By considering one such X_λ at a time, we may assume without loss of generality that $X = X_\lambda$. Since for each ∂_{ζ_k} and fixed λ , the exponent vector μ is uniquely determined, we can rewrite X as

$$X = \sum_{k=1}^{2n} c_{\lambda+e_k}^k \zeta^{\lambda+e_k} \partial_{\zeta_k}.$$

In general, the coordinates of $\lambda + e_k$ must be nonnegative, so the coordinates of λ must be greater than or equal to -1 with at most one coordinate equal to -1 . When $\lambda = 0$ in \mathbb{Z}^{2n} , then X_λ is a linear combination of $\zeta_1 \partial_{\zeta_1}, \dots, \zeta_{2n} \partial_{\zeta_{2n}}$. If $\lambda_\ell = -1$, then X is the single term $X = c \zeta^{\lambda+e_\ell} \partial_{\zeta_\ell}$ for some $c \in \mathbb{C}$.

Suppose $\lambda_\ell = -1$ with $\ell \leq n$ and translate back in terms of z and w , so that $X = c z^\alpha w^\beta \partial_{z_\ell}$ and $\alpha_\ell = 0$. Applying (3.4), we can compute $\sigma(X)$ and see that the coefficient of $\partial_{z_\ell} \wedge \partial_{w_q}$ in $\sigma(X)$ is $(B_q \cdot (\alpha - e_\ell)) w_q z^\alpha w^\beta$ for each q . Since B is invertible and $\alpha - e_\ell \neq 0$, then $\sigma(X) \neq 0$. Similarly, by applying (3.5) we can deduce the same conclusion if $\ell > n$. Thus if $X = X_\lambda$ is in the kernel of σ , we may assume that all coordinates of λ are nonnegative and so

$$(3.6) \quad X = X_\lambda = \sum_{j=1}^n a^j z^{\alpha+e_j} w^\beta \partial_{z_j} + \sum_{j=1}^n b_{\alpha,\beta}^j z^\alpha w^{\beta+e_j} \partial_{w_j}$$

for $\lambda = (\alpha, \beta)$ and some coefficients $a_{\alpha,\beta}^j$ and $b_{\alpha,\beta}^j$. Applying (3.4) and (3.5) to (3.6), we find that

$$(3.7) \quad \sigma(X) = X \wedge \left(\sum_{p=1}^n (B_p \cdot \beta) z_p \partial_{z_p} - \sum_{q=1}^n (B_q \cdot \alpha) w_q \partial_{w_q} \right).$$

Another straightforward computation with the Schouten bracket shows that

$$(3.8) \quad \sigma(z^\alpha w^\beta) = z^\alpha w^\beta \left(\sum_{p=1}^n (B_p \cdot \beta) z_p \partial_{z_p} - \sum_{q=1}^n (B_q \cdot \alpha) w_q \partial_{w_q} \right).$$

Thus, if $X = X_\lambda \neq 0$ satisfies $\sigma(X) = 0$, then $X \wedge \sigma(z^\alpha w^\beta) = 0$ by (3.7) and (3.8). Hence, if $\sigma(z^\alpha w^\beta) \neq 0$ then $X = c \sigma(z^\alpha w^\beta)$ for some $c \neq 0$. If $(\alpha, \beta) = (0, 0)$, then $\sigma(z^\alpha w^\beta) = 0$ by inspection of (3.8). On the other hand, if $(\alpha, \beta) \neq (0, 0)$, then $\sigma(z^\alpha w^\beta) \neq 0$ because $[B_{pq}]$ is invertible. Thus, $X = c \sigma(z^\alpha w^\beta) = \sigma(c z^\alpha w^\beta)$ when $(\alpha, \beta) \neq (0, 0)$. This completes the proof. \square

FIGURE 1. Dimensions of $H_{[d]}^p(\mathbb{C}^2, zw\partial_z \wedge \partial_w)$ up to $d = 6$.

3.2. Algebraic Cohomology for $n = 1$. When $n = 1$, the matrix $[B_{pq}]$ is 1×1 consisting of a single non-zero complex number. Hence $\pi_B = b zw \partial_z \wedge \partial_w$. As mentioned before, an overall non-zero scalar multiple of a Poisson tensor does not affect its cohomology, so we can more simply consider $\pi = zw \partial_z \wedge \partial_w$. By Prop. 3.1 and Theorem 3.2, we know that

$$H^0(\mathbb{C}^2, b zw \partial_z \wedge \partial_w) = \mathbb{C}\langle 1 \rangle \text{ and } H^1(\mathbb{C}^2, b zw \partial_z \wedge \partial_w) = \mathbb{C}\langle z \partial_z, w \partial_w \rangle$$

for each $b \neq 0$. It remains then to determine $H^2(\mathbb{C}^2, b zw \partial_z \wedge \partial_w)$ which is the space of all bi-vector fields on \mathbb{C}^2 modulo the subspace of the image of σ in wedge degree 2. At this point, let us observe that the cochain complex $R \otimes \bigwedge V$ can be graded not only by the wedge degree from the second factor $\bigwedge V$ but also using the total homogeneous degree on the polynomial ring R . The Poisson differential σ , which raises the wedge degree by 1 also raises the homogeneous degree by 1 because its action on a multi-vector field involves 1st order differentiation of coefficients post-multiplied by a homogeneous quadratic expression. The cohomology $H(\mathbb{C}^2, \pi)$ then has a direct sum decomposition

$$H(\mathbb{C}^2, \pi) = \bigoplus_{d \in \mathbb{N}} \bigoplus_{p=0}^2 H_{[d]}^p(\mathbb{C}^2, \pi)$$

where

$$H_{[d]}^p(\mathbb{C}^2, \pi) = \frac{\ker \sigma: R_{[d]} \otimes \bigwedge^p V \rightarrow R_{[d+1]} \otimes \bigwedge^{p+1} V}{\operatorname{im} \sigma: R_{[d-1]} \otimes \bigwedge^{p-1} V \rightarrow R_{[d]} \otimes \bigwedge^p V}.$$

In particular, the bi-vector field $\partial_z \wedge \partial_w$ which generates $R_{[0]} \otimes \bigwedge^2 V$ is certainly not in the image of σ and so $H_{[0]}^2(\mathbb{C}^2, \pi) = \mathbb{C}\langle \partial_z \wedge \partial_w \rangle$. The next result completes the computation of the complex algebraic cohomology. See Figure 1. Intriguingly, this recovers the same result found by Nakanishi in [7],

$$H(\mathbb{C}^2, zw \partial_z \wedge \partial_w) = \mathbb{C}\langle 1, z \partial_z, w \partial_w, \partial_z \wedge \partial_w, zw \partial_z \wedge \partial_w \rangle$$

except that he considered real coefficients, with z and w as real variables, and used analytic techniques to classify the solutions to the partial differential equations encoded in $\sigma(Y) = 0$.

Proposition 3.3. *For $b \neq 0$,*

$$H^2(\mathbb{C}^2, b zw \partial_z \wedge \partial_w) \simeq \mathbb{C}\langle \partial_z \wedge \partial_w, zw \partial_z \wedge \partial_w \rangle$$

for the complex algebraic cohomology.

Proof. As we observed before, $H(\mathbb{C}^2, b zw \partial_z \wedge \partial_w) = H(\mathbb{C}^2, zw \partial_z \wedge \partial_w)$. We will compute $H_{[d]}^2(\mathbb{C}^2, b zw \partial_z \wedge \partial_w) = 0$ for each $d \geq 1$. Let $d \geq 1$ be given. Since $\ker \sigma \cap (R_{[d]} \otimes \bigwedge^2 V) = R_{[d]} \otimes \bigwedge^2 V$, it suffices to show that every basis element of the form $z^p w^q \partial_z \wedge \partial_w$, where $p + q = d$ with $d \neq 2$, has a primitive with respect to σ . Consider a general element $X \in R_{[d-1]} \otimes \bigwedge^1 V$ of the form

$$X = \sum_{\alpha, \beta} a_{\alpha\beta} z^\alpha w^\beta \partial_z + \sum b_{\gamma, \delta} z^\gamma w^\delta \partial_w$$

where the sums are over pairs of non-negative integers which sum to $d - 1$. A straightforward calculation with the Schouten bracket shows that

$$\begin{aligned} \sigma(X) = & -(-a_{0,d-1} w^d + b_{0,d-1}(d-2)zw^{d-1} \\ & + \sum (a_{p,q-1}(p-1) + b_{p-1,q}(q-1))z^p w^q \\ & + a_{d-1,0}(d-2)z^{d-1}w - b_{d-1,0}z^d) \partial_z \wedge \partial_w \end{aligned} \quad (3.9)$$

where the sum is over $p, q \geq 2$ with $p + q = d$. From this formula, it follows that the basis elements

$$w^d \partial_z \wedge \partial_w, \quad z^d \partial_z \wedge \partial_w$$

have unique primitives with respect to σ and the basis elements

$$zw^{d-1} \partial_z \wedge \partial_w, \quad z^{d-1} w \partial_z \wedge \partial_w$$

have unique primitives with respect to σ provided $d \neq 2$. The basis elements $z^p w^q \partial_z \wedge \partial_w$ with $p, q \geq 2$ have one parameter families of primitives. The only basis vectors of $R \otimes \bigwedge^2 V$ which are not accounted for are $\partial_z \wedge \partial_w$ and $zw \partial_z \wedge \partial_w$. As we already observed, the first cannot be in the image of σ . Examining the formula above for $\sigma(X)$ when $d = 2$, we see that $zw \partial_z \wedge \partial_w$ does not appear either. Therefore, $H_{[d]}^2 = \mathbf{0}$ unless $d = 2$, in which case $H_{[2]}^2 = \mathbb{C}\langle zw \partial_z \wedge \partial_w \rangle$. \square

3.3. Numerical Results H^* when $n = 2$. When $n = 2$, we are considering the Poisson cohomology $H(\mathbb{C}^4, \pi_B)$ in the complex algebraic category where

$$\pi_B = B_{11} z_1 w_1 \partial_{z_1} \wedge \partial_{w_1} + B_{12} z_1 w_2 \partial_{z_1} \wedge \partial_{w_2} + B_{21} z_2 w_1 \partial_{z_2} \wedge \partial_{w_1} + B_{22} z_2 w_2 \partial_{z_2} \wedge \partial_{w_2}$$

for some matrix

$$B = \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix}.$$

With the increase in the number of variables and the number of terms in π_B , comes an increase in complexity of the cohomological computations, even for the algebraic problem. Still, σ in this context raises wedge degree by 1 and total homogeneous degree by 1, so the cochain complex $R \otimes \bigwedge V$ decomposes as a direct sum of cochain complexes $(\bigoplus_{p=0}^4 R_{[d+p]} \otimes \bigwedge^p V, \sigma)$ over d from $-2n$ to ∞ , where we set $R_{[\ell]} \otimes \bigwedge^p V = \mathbf{0}$ if $\ell < 0$. While $R \otimes \bigwedge^p V$ is infinite dimensional, each $R_{[d]} \otimes \bigwedge^p V$ is finite dimensional with

$$\dim_{\mathbb{C}} R_{[d]} \otimes \bigwedge^p V = \binom{d+2n-1}{2n-1} \binom{2n}{p}.$$

Thus, $\sigma: R_{[d]} \otimes \bigwedge^p V \rightarrow R_{[d+1]} \otimes \bigwedge^{p+1} V$ has a matrix representation, and linear algebra can be used to determine each $H_{[d]}^p(\mathbb{C}^4, \pi_B)$. For brevity, let's write $\sigma_{[d]}^p$ for $\sigma: R_{[d]} \otimes \bigwedge^p V \rightarrow R_{[d+1]} \otimes \bigwedge^{p+1} V$.

We were able to use Mathematica 10 to perform these computations for small d up to $d = 8$ with fairly fast computing times on a 2.7GHz processor with 8GB of

$B = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$						$B = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$					
$\dim H_{[d]}^p$	0	1	2	3	4	$\dim H_{[d]}^p$	0	1	2	3	4
0	1	0	2	0	1	0	1	0	0	0	1
1	0	4	0	4	0	1	0	4	0	0	0

RAM. The dimension of $R_{[d]} \otimes \bigwedge^p V$ grows fairly quickly with d and consequently the matrices representing each $\sigma_{[d]}^p$ get large fairly quickly. For example, $\sigma_{[8]}^2$ is represented by an 880×990 matrix.

Our computations involved a mix of symbolic computation and linear algebra. If we write $z^p w^q$ for the monomial $z_1^{p_1} z_2^{p_2} w_1^{q_1} w_2^{q_2}$ determined by $(p, q) \in \mathbb{N}^2 \times \mathbb{N}^2$ and likewise write $\partial_z^\gamma \partial_w^\delta$ for $\partial_{z_1}^{\gamma_1} \partial_{z_2}^{\gamma_2} \partial_{w_1}^{\delta_1} \partial_{w_2}^{\delta_2}$ in $\bigwedge V$ determined by $(\gamma, \delta) \in \{0, 1\}^2 \times \{0, 1\}^2$, then we obtain a \mathbb{C} -basis $\{z^p w^q \partial_z^\gamma \partial_w^\delta\}$ for $R_{[d]} \otimes \bigwedge^p V$ indexed by all (p, q) with $p_1 + p_2 + q_1 + q_2 = d$ and (γ, δ) with $\gamma_1 + \gamma_2 + \delta_1 + \delta_2 = p$. Determining the matrix representing $\sigma_{[d]}^p$ in terms of these bases involved symbolic computation, implementing calculations with the Schouten bracket. Once the matrix representations were found, computing $H_{[d]}^p$ reduced to the following linear algebra.

- (1) Using Gauss-Jordan Elimination, we can determine a basis for the column space of the matrix representing $\sigma_{[d-1]}^{p-1}$ and determine the corresponding symbolic basis for $\text{im } \sigma_{[d-1]}^{p-1}$.
- (2) Next we find a basis for the null space of the matrix representing $\sigma_{[d]}^p$ and determine the corresponding symbolic basis for $\ker \sigma_{[d]}^p$.
- (3) If we form a matrix whose rows are the basis vectors of the column space for $\sigma_{[d-1]}^{p-1}$ (written as rows) followed by the basis vectors for the null space of the matrix for $\sigma_{[d]}^p$ (written as rows) and then perform Gauss-Jordan Elimination on this matrix we obtain a matrix in reduced row echelon form.
- (4) If the basis for the column space of $\sigma_{[d-1]}^{p-1}$ had k elements, then the upper left $k \times k$ block of this reduced matrix will be the identity. The remaining non-zero rows, rewritten as columns, form a basis for a subspace of the null space of the matrix for $\sigma_{[d]}^p$ which is complementary to column space of the matrix for $\sigma_{[d-1]}^{p-1}$. The corresponding symbolic vectors are representatives for a basis of $H_{[d]}^p$.

$$B = \begin{pmatrix} 3 & -1 \\ -1 & 2 \end{pmatrix} \quad B = \begin{pmatrix} 6 & -2 \\ -2 & 2 \end{pmatrix} \quad B = \begin{pmatrix} 11 & -3 \\ -3 & 2 \end{pmatrix}$$

$\dim H_{[d]}^p$	0	1	2	3	4	$\dim H_{[d]}^p$	0	1	2	3	4	$\dim H_{[d]}^p$	0	1	2	3	4
0	1	0	0	0	1	0	1	0	0	2	1	0	1	0	0	0	1
1	0	4	0	0	0	1	0	4	0	2	2	1	0	4	0	0	0
2	0	0	6	0	0	2	0	0	6	2	2	2	0	0	6	0	0

FIGURE 3. Cohomological dimensions up to $d = 8$ for the three cases shown.

We considered quadratic forms B whose matrices $[B_{ij}]$ had one of five forms

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}, \begin{pmatrix} 2+m^2 & -m \\ -m & 2 \end{pmatrix} \text{ for } m = 1, 2, 3.$$

These give local forms for the toric Poisson structures constructed in [1] on the smooth toric varieties $\mathbb{CP}^1 \times \mathbb{CP}^1$, \mathbb{CP}^2 , and the Hirzebruch surfaces X_m for $m = 1, 2, 3$, respectively. Figures 2 and 3 show the cohomological dimensions computed for each of these cases for $0 \leq p \leq 4$ and $0 \leq d \leq 8$. In each of these cases, the elements $z^\gamma w^\delta \partial_z^\gamma \partial_w^\delta$ in $R \otimes \bigwedge V$ represent classes in the basis for H . Furthermore, the diagonal $\bigoplus_{k=0}^4 H_{[k]}^k = \bigwedge \mathbb{C} \langle z_1 \partial_{z_1}, z_2 \partial_{z_2}, w_1 \partial_{w_1}, w_2 \partial_{w_2} \rangle$ is generated by the basis vector fields generating the $\mathbb{T}_{\mathbb{C}}^4$ action on \mathbb{C}^4 . Let us refer to the basis vectors of $R \otimes \bigwedge V$ of this type as those of Type I. The additional classes in each basis were, remarkably, also represented by basis vectors of \mathcal{V} which lie in $\ker \sigma$ but are of one of two other types. The generators of Type II were $z^\alpha w^\beta \partial_{z^\gamma w^\delta}$ in $\ker \sigma$ with the property that $\alpha \cdot \gamma = 0$ and $\beta \cdot \delta = 0$. Those of the remaining Type III were non-zero wedge products of generators of Type I and Type II. Thus, it appears that the cohomology is generated as a module over the diagonal $\bigoplus_{k=0}^4 H_{[k]}^k = \bigwedge \mathbb{C} \langle z_1 \partial_{z_1}, z_2 \partial_{z_2}, w_1 \partial_{w_1}, w_2 \partial_{w_2} \rangle$ by 1 and the basis vectors of $R \otimes \bigwedge V$ which lie in the kernel of σ and are of Type II. In a forthcoming paper, we use representation theory to show that such a presentation of the cohomology as a module over $\bigwedge \mathfrak{t}_{\mathbb{C}}$ is possible for any n and B .

Example 3.4. For $B = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$, the cohomology up to homogeneous degree 8 generated as a module over the diagonal by $1, \partial_{z_1} \wedge \partial_{w_1}, \partial_{z_2} \wedge \partial_{w_2}, \partial_{z_1} \wedge \partial_{z_2} \wedge \partial_{w_1} \wedge \partial_{w_2}$.

Example 3.5. For $B = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$, the cohomology up to homogeneous degree 8 is generated as a module over the diagonal by $1, z_1^2 w_2^2 \partial_{z_2} \wedge \partial_{w_1}, z_2^2 w_1^2 \partial_{z_1} \wedge \partial_{w_2}$, and $\partial_{z_1} \wedge \partial_{z_2} \wedge \partial_{w_1} \wedge \partial_{w_2}$.

Example 3.6. For $B = \begin{pmatrix} 3 & -1 \\ -1 & 2 \end{pmatrix}$, the cohomology up to homogeneous degree 8 is generated as a module over the diagonal by 1 and $\partial_{z_1} \wedge \partial_{z_2} \wedge \partial_{w_1} \wedge \partial_{w_2}$.

Example 3.7. For $B = \begin{pmatrix} 6 & -2 \\ -2 & 2 \end{pmatrix}$, the cohomology up to homogeneous degree 8 is generated as a module over the diagonal by 1 and $\partial_{z_1} \wedge \partial_{z_2} \wedge \partial_{w_1} \wedge \partial_{w_2}$ and $z_2^d \partial_{z_1} \wedge \partial_{w_1} \wedge \partial_{w_2}, w_2^d \partial_{z_1} \wedge \partial_{z_2} \wedge \partial_{w_1}$ for each $0 \leq d \leq 8$. In fact, we can show that these latter expressions are generators of the full cohomology for every degree d . Thus, the algebraic cohomology of this Poisson structure on \mathbb{C}^4 is infinite dimensional despite the fact that B is integral and symmetric positive definite.

Example 3.8. For $B = \begin{pmatrix} 11 & -3 \\ -3 & 2 \end{pmatrix}$, the cohomology up to homogeneous degree 8 is generated as a module over the diagonal by 1 and $\partial_{z_1} \wedge \partial_{z_2} \wedge \partial_{w_1} \wedge \partial_{w_2}$.
